

# Operators and Condition Evaluation

## Relational and Logical Operators

- *A condition* is an expression
  - Involving relational operators (such as < and >=)
  - Logical operators (such as and, or, and not)
  - Evaluates to either True or False
- Conditions used to make decisions
  - Control loops
  - Choose between options

# Relational Operators

- Relational operator *less than* (<) can be applied to
  - Numbers
  - Strings
  - Other objects
- For strings, the ASCII table determines order of characters

# Relational Operators

Python Notation	Numeric Meaning	String Meaning
==	equal to	identical to
!=	not equal to	different from
<	less than	precedes lexicographically
>	greater than	follows lexicographically
<=	less than or equal to	precedes lexicographically or is identical to
>=	greater than or equal to	follows lexicographically or is identical to
in		substring of
not in		not a substring of

Relational operators

# ASCII Values

- ASCII values determine order used to compare strings with relational operators.
- Associated with keyboard letters, characters, numerals
  - ASCII values are numbers ranging from 32 to 126.
- A few ASCII values.

32 (space)	48 0	66 B	122 z
33 !	49 1	90 Z	123 {
34 "	57 9	97 a	125 }
35 #	65 A	98 b	126 ~

# ASCII Values

- The ASCII standard also assigns characters to some numbers above 126.
- A few of the higher ASCII values.

162 ¢	177 ±	181 μ	190 ¾
169 ©	178 <sup>2</sup>	188 ¼	247 ÷
176 °	179 <sup>3</sup>	189 ½	248 ø

- Functions `chr(n)` and `ord(str)` access ASCII values

# Relational Operators

- Example: Determine whether following conditions evaluate to *True* or *False*

(a)  $1 \leq 1$

(b)  $1 < 1$

(c) "car" < "cat"

(d) "Dog" < "dog"

(e) "fun" in "refunded"

# Relational Operators

- Example: Determine whether following conditions evaluate to *True* or *False*

*(a=4, b=3, c="hello", d="bye")*

**(a)**  $(a + b) < (2 * a)$

**(b)**  $(\text{len}(c) - b) == (a/2)$

**(c)**  $c < (\text{"good"} + d)$

- *len()* is a function that returns the length of a string

# Relational Operators

- Some rules
  - An int *can* be compared to a float.
  - Otherwise, values of different types *cannot* be compared
  - \*\*Relational operators can be applied to lists or tuples

`[3, 5] < [3, 7]`

`[3, 5] < [3, 5, 6]`

`[3, 5, 7] < [3, 7, 2]`

`[7, "three", 5] < [7, "two", 2]`

# Logical Operators

- Based on Boolean algebra (input values are boolean rather than numbers)
- In mathematics and mathematical logic, Boolean algebra is the branch of algebra in which the values of the variables are the truth values true and false, usually denoted 1 and 0 respectively
- Elementary algebra works with the values of the variables that are numbers, and the prime operations are addition and multiplication
- Boolean algebra works with 0s and 1s as input values, the main operations of Boolean algebra are the conjunction (and) denoted as  $\wedge$ , the disjunction (or) denoted as  $\vee$ , and the negation (not) denoted as  $\neg$ .
- Boolean algebra is a formalism for describing logical operations in the same way that elementary algebra describes numerical operations.

# Logical Operators

- Logical operators enable combining conditions which are likely to use relational operators
- Logical operators are the reserved words **and, or, not**
- Conditions that use these operators are called compound conditions

# Logical Operators

- Given: *cond1* and *cond2* are conditions
  - **cond1 and cond2** true only if both conditions are true  
Example: (a == 3 and b == 5)
  - **cond1 or cond2** true if either or both conditions are true  
Example: (a == 3 or c < 10)
  - **not cond1** is false if the condition is true, true if the condition is false  
Example: not(a < b)

# Logical Operators

Operator	Truth Table															
AND	<table><tr><th>A</th><th>B</th><th>A and B</th></tr><tr><td>True</td><td>True</td><td>True</td></tr><tr><td>True</td><td>False</td><td>False</td></tr><tr><td>False</td><td>True</td><td>False</td></tr><tr><td>False</td><td>False</td><td>False</td></tr></table>	A	B	A and B	True	True	True	True	False	False	False	True	False	False	False	False
A	B	A and B														
True	True	True														
True	False	False														
False	True	False														
False	False	False														
OR	<table><tr><th>A</th><th>B</th><th>A or B</th></tr><tr><td>True</td><td>True</td><td>True</td></tr><tr><td>True</td><td>False</td><td>True</td></tr><tr><td>False</td><td>True</td><td>True</td></tr><tr><td>False</td><td>False</td><td>False</td></tr></table>	A	B	A or B	True	True	True	True	False	True	False	True	True	False	False	False
A	B	A or B														
True	True	True														
True	False	True														
False	True	True														
False	False	False														
NOT	<table><tr><th>A</th><th>not A</th></tr><tr><td>True</td><td>False</td></tr><tr><td>False</td><td>True</td></tr></table>	A	not A	True	False	False	True									
A	not A															
True	False															
False	True															

# Operator Precedence

- Operator Precedence from Highest to Lowest

TYPE OF OPERATOR	OPERATOR SYMBOL
Exponentiation	<b>**</b>
Arithmetic negation	<b>-</b>
Multiplication, division, remainder	<b>*, /, %</b>
Addition, subtraction	<b>+, -</b>
Comparison	<b>==, !=, &lt;, &gt;, &lt;=, &gt;=</b>
Logical negation	<b>not</b>
Logical conjunction and disjunction	<b>and, or</b>
Assignment	<b>=</b>

# Logical Operators

- Example: Given  $n = 4$ ,  $\text{answ} = \text{"Y"}$  Determine expressions = *True* or *False*

- (a)  $(2 < n) \text{ and } (n < 6)$
- (b)  $(2 < n) \text{ or } (n == 6)$
- (c)  $\text{not } (n < 6)$
- (d)  $(\text{answ} == \text{"Y"}) \text{ or } (\text{answ} == \text{"y"})$
- (e)  $(\text{answ} == \text{"Y"}) \text{ and } (\text{answ} == \text{"y"})$
- (f)  $\text{not } (\text{answ} == \text{"y"})$
- (g)  $((2 < n) \text{ and } (n == 5 + 1)) \text{ or } (\text{answ} == \text{"No"})$
- (h)  $((n == 2) \text{ and } (n == 7)) \text{ or } (\text{answ} == \text{"Y"})$
- (i)  $(n == 2) \text{ and } ((n == 7) \text{ or } (\text{answ} == \text{"Y"}))$

# The `bool` Data Type

- Objects `True` and `False` are said to have Boolean data type
  - Of data type `bool`.
- What do these lines display?

```
x = 2
y = 3
var = x < y
print(var)
```

```
x = 5
print((3 + x) < 7)
```

# Simplifying Conditions

Use of De Morgan's Laws – allows us to simplify complementing a logical expression

- How do we express that  $x$  is between the range 10 (not including 10) and 20 (including 20)?

```
x > 10 and x <= 20
```

- Suppose we want to find the complement of this condition i.e.  $x$  is not within this specified range

```
not(x > 10 and x <= 20)
```

# Simplifying Conditions

Using De Morgan's laws:

`(not(cond1 and cond2))`

is the same as

`not(cond1) or not(cond2)`

i.e. complement each individual condition and complement the logical operator joining the two conditions

`not(x > 10 and x <= 20) ----> x <= 10 or x > 20`

- Similarly:

`not(cond1 or cond2)`

is the same as

`not(cond1) and not(cond2)`

# Simplifying Conditions

Also note that Python supports this syntax:

```
(x > 10) and (x <= 20)
```

can be replaced with the condition

```
10 < x <= 20
```

```
(x <= 10) or (x > 20)
```

can be replaced with the condition

```
not (10 < x <= 20)
```

# Short-Circuit Evaluation

- Consider the condition **cond1 and cond2**
  - If Python evaluates **cond1** as false, it does not bother to check **cond2**
- Similarly with **cond1 or cond2**
  - If Python finds **cond1** true, it does not bother to check further
- Think why this feature helps for  
**(number != 0) and (m == (n / number))**
